# 1 Introduction and Motivation

---

## 1.1 Context

This report presents the design, implementation, and evaluation of Chirp (Compact Hub for Instant Real-time Posting), a simplified Twitter clone developed as part of the "205.2 Beyond relational databases" course. The project demonstrates the application of key-value database concepts using Redis, moving beyond traditional relational database paradigms to explore alternative data modeling approaches.

## 1.2 Project Objectives

The primary objectives of this laboratory project were:

1. Learn to model a practical data-intensive application as a key-value database
2. Translate application requirements into implementation tasks and data modeling
3. Implement and interact with a key-value store from a programmatic perspective

## 1.3 Motivation

Social media platforms represent one of the most challenging use cases for database systems due to their high write throughput, complex data relationships, and need for real-time access. By implementing a Twitter-like service with Redis, this project provides hands-on experience with non-relational database patterns that can handle these requirements effectively.

Twitter (now X) serves as an excellent model for this exercise since it has well-defined core functionalities that lend themselves to key-value representation. The ability to post short messages, follow users, and retrieve timelines aligns well with the strengths of key-value stores like Redis, which excel at fast read/write operations and sorted collections.

# 2 Project Repository

---

## 2.1 Repository Link

The complete codebase for this project is available at:

<https://github.com/jjigiduc/chirp-redis-keyvalue-lab>

## 2.2 Repository Structure

The repository follows a clean, professional organization with the following structure:

```
chirp-redis-keyvalue-lab/  
|-- README.md           # Installation and usage instructions  
|-- requirements.txt     # Main dependencies  
|-- requirements-dev.txt # Development dependencies  
|-- src/                # Main source code
```

```
| |-- app/                                # Application code
| | |-- __init__.py
| | |-- chirp_app.py                    # Command-line application
| | |-- streamlit_app.py                # Web application
| |-- models/                           # Redis data models
| | |-- __init__.py
| | |-- redis_model.py                  # Core Redis data model implementation
|-- scripts/                             # Utility scripts
| |-- import_data.py                    # Data import script
| |-- process_jsonl.py                  # Data processing script
| |-- reset_db.py                       # Database reset script
| |-- run_app.py                        # Application launcher
| |-- run_tests.py                      # Test runner
| |-- fix_engagement.py                 # Script to add engagement metrics
|-- data/                                # Generated data
| |-- processed/                        # Processed data directory
|-- tests/                               # Test suite
| |-- __init__.py
| |-- conftest.py                       # Pytest configuration
| |-- test_redis_model.py               # Tests for Redis model
| |-- test_import_data.py               # Tests for data import
| |-- test_streamlit_app.py             # Tests for web interface
```

## 2.3 Installation and Usage

To install and run the application:

```
1 # Clone the repository
2 git clone https://github.com/jijiduc/chirp-redis-keyvalue-lab.git
3 cd chirp-redis-keyvalue-lab
4
5 # Install required dependencies
6 pip install -r requirements.txt
7
8 # Optional: Install development dependencies for testing
9 pip install -r requirements-dev.txt
10
11 # Start Redis (if not running)
12 sudo systemctl start redis-server # On Linux
13 # Or manually: redis-server
14
15 # Process and import sample data
16 python scripts/process_jsonl.py --generate-sample
17 python scripts/import_data.py ./data/processed/sample_english_tweets.json --add-
   engagement
18
19 # Run the command line application
20 python scripts/run_app.py
21
22 # Run the web interface
23 streamlit run src/app/streamlit_app.py
```

Listing 1: Installation and setup commands

The README.md file in the repository contains comprehensive instructions for setting up the development environment, running the application, and executing the test suite. It also provides

detailed information about the available commands and how to interact with the application.

## 3 Requirements Clarification and Assumptions

---

### 3.1 Core Requirements

Based on the laboratory instructions, the minimal requirements for the Chirp application were:

- **Following/followers:** Each user can have followers and follow other users
- **Chirps:** Users can post small text-only messages in English
- **Rankings:** The system must track and display various rankings:
  - Top 5 users with highest follower counts
  - Top 5 users with most chirps
  - List of 5 latest chirps

### 3.2 Assumptions

Several assumptions were made to guide the implementation:

1. **Unidirectional relationship model:** Following is unidirectional, meaning if user A follows user B, it doesn't imply that B follows A
2. **Limited timeline size:** To prevent memory exhaustion, the timeline will be capped at 100,000 entries
3. **No tweet deletion:** For simplicity, the initial version doesn't support chirp deletion
4. **Simple authentication:** User authentication is not implemented in this version
5. **English-only content:** As specified in the requirements, only English chirps are considered
6. **Engagement metrics:** Additional engagement metrics (likes, rechirps) were added to make the application more realistic

### 3.3 Design Decisions

Several key decisions guided the implementation strategy:

1. **Python as primary language:** Python was chosen for its excellent Redis library support and ability to rapidly prototype the application
2. **Separation of concerns:** The implementation strictly separates the data model, command-line interface, and web interface to ensure maintainability
3. **Streamlit for web interface:** Streamlit was selected for the web interface due to its simplicity and rapid development capabilities
4. **Redis as the sole database:** All data is stored in Redis with no secondary storage systems
5. **Unit testing:** Comprehensive unit tests were implemented to ensure reliability
6. **Import pipeline:** A data import pipeline was created to populate the system with realistic Twitter data

## 4 Data Modeling as Key-Value

---

### 4.1 Key Design Principles

The data model was designed around several key principles specific to key-value databases:

1. **Denormalization:** Data is intentionally duplicated where necessary to optimize read performance. For example:
  - Username is stored in both user records and chirp records to avoid additional lookups
  - Follower and chirp counts are stored in user records instead of being calculated on demand
  - Engagement metrics (likes, retweets) are stored directly in chirp records
2. **Composite keys:** Meaningful prefixes are used to organize related data:
  - `users:{user_id}` for user profiles
  - `chirp:{chirp_id}` for individual posts
  - `users:top_followers` for follower rankings
  - `chirps:timeline` for the global timeline
3. **Appropriate data structures:** Redis data types are selected based on access patterns:
  - Hashes for complex entities (users, chirps)
  - Sorted sets for rankings and timeline (with timestamp or count as score)
  - Regular hash for username-to-ID mapping
4. **Indexing for fast lookups:** Secondary indices are created for frequently queried attributes:
  - Username-to-ID mapping for quick user lookups
  - Temporary sorted sets for engagement-based rankings
5. **Score-based sorting:** Timestamps and counts are used as scores in sorted sets for efficient ranking:
  - Timestamps for chronological timeline sorting
  - Follower counts for popularity ranking
  - Engagement metrics for trending content

### 4.2 Data Models

#### 4.2.1 User Model

Users are modeled using Redis hashes with the key pattern `users:{user_id}`:

```
1 # User hash example (users:123456789)
2 {
3     "username": "testuser",
4     "name": "Test User",
5     "follower_count": 100,
6     "following_count": 50,
```

```
7   "chirp_count": 200,  
8   "created_at": "Mon Apr 01 12:00:00 +0000 2025",  
9   "profile_image": "https://example.com/image.jpg"  
10 }
```

Listing 2: User data structure in Redis

For quick username lookups, a separate hash maps usernames to user IDs:

```
1 # Username index (usernames)  
2 {  
3   "testuser": "123456789",  
4   "anotheruser": "987654321",  
5   ...  
6 }
```

Listing 3: Username to user ID mapping

## 4.2.2 Chirp Model

Chirps (tweets) are stored as hashes with the key pattern `chirp:{chirp_id}`:

```
1 # Chirp hash example (chirp:987654321)  
2 {  
3   "text": "This is a test chirp!",  
4   "user_id": "123456789",  
5   "username": "testuser",  
6   "created_at": "Mon Apr 01 12:30:00 +0000 2025",  
7   "lang": "en",  
8   "favorite_count": 10,  
9   "retweet_count": 5  
10 }
```

Listing 4: Chirp data structure in Redis

## 4.2.3 Timeline and Rankings

Redis sorted sets are used for the timeline and user rankings:

```
1 # Global timeline (chirps:timeline)  
2 # Format: chirp_id -> timestamp  
3 # Sorted by timestamp for chronological order  
4 {  
5   "987654321": 1712055000.0,  
6   "987654322": 1712055060.0,  
7   ...  
8 }  
9  
10 # Top users by followers (users:top_followers)  
11 # Format: user_id -> follower_count  
12 # Sorted by follower count  
13 {  
14   "123456789": 100,  
15   "987654321": 200,  
16   ...  
17 }  
18
```

```
19 # Top users by chirp count (users:top_posters)
20 # Format: user_id -> chirp_count
21 # Sorted by chirp count
22 {
23     "123456789": 200,
24     "987654321": 150,
25     ...
26 }
```

Listing 5: Timeline and ranking data structures

### 4.3 Data Relationships

Relationships between entities are modeled through:

1. **Reference by ID:** Chirps contain `user_id` to establish ownership
2. **Denormalized fields:** Usernames are duplicated in chirp records for performance
3. **Counters:** Follower/following counts are maintained in user records
4. **Sorted sets:** Used to maintain relationships with additional metadata (timestamps, counts)

This approach differs from traditional relational databases where relationships would be maintained through foreign keys and joins. In our Redis implementation, denormalization plays a critical role in achieving performance at scale. The trade-off is increased storage requirements and the need to ensure data consistency when updating records (for example, when a user posts a new chirp, we must update both the timeline and the user's chirp count).

## 5 Software Architecture and Functionalities

### 5.1 System Architecture

The Chirp application is organized into a layered architecture:

|   |
|---|
| <b>Presentation Layer</b><br>Command-line Interface (CLI) / Streamlit Web Interface |
| <b>Application Layer</b><br>ChirpApp (Business Logic)                               |
| <b>Data Access Layer</b><br>ChirpRedisModel (Data Model)                            |
| <b>Database</b><br>Redis  |

Figure 1: Architectural layers of the Chirp application

The project is structured as follows:

```
chirp-redis-keyvalue-lab/
|-- src/                                # Main source code
|   |-- app/                            # Application code
|       |-- __init__.py
|       |-- chirp_app.py                # Command-line application
|       |-- streamlit_app.py            # Web application
|   |-- models/                         # Redis data models
|       |-- __init__.py
|       |-- redis_model.py              # Core Redis data model implementation
|-- scripts/                            # Utility scripts
|   |-- import_data.py                  # Data import script
|   |-- process_jsonl.py                # Data processing script
|   |-- reset_db.py                     # Database reset script
|   |-- run_app.py                      # Application launcher
|   |-- fix_engagement.py                # Script to add engagement metrics
|-- data/                               # Generated data
|   |-- processed/                      # Processed data directory
|-- tests/                              # Test suite
|   |-- __init__.py
|   |-- conftest.py
|   |-- test_redis_model.py
|   |-- test_import_data.py
|   |-- test_streamlit_app.py
```

### 5.2 Core Components

#### 5.2.1 Data Model (ChirpRedisModel)

The data model class encapsulates all interactions with Redis, providing an abstraction layer for the application logic:

```
1 class ChirpRedisModel:
2     # Core methods
3     def import_user(self, user_data): ...
4     def import_chirp(self, chirp_data): ...
5     def get_latest_chirps(self, count=5): ...
6     def get_top_users_by_followers(self, count=5): ...
7     def get_top_posters(self, count=5): ...
8     def post_chirp(self, user_id, text): ...
9     def like_chirp(self, chirp_id): ...
10    def rechirp(self, chirp_id): ...
11    def add_user(self, username, name, profile_image=''): ...
12    def get_top_liked_chirps(self, count=5): ...
13    def get_top_rechirped_chirps(self, count=5): ...
14    def reset_db(self): ...
```

Listing 6: Key methods in the ChirpRedisModel class

## 5.2.2 Command-line Interface (ChirpApp)

The CLI provides an interactive interface to the Chirp functionality:

```
1 class ChirpApp:
2     def __init__(self, host='localhost', port=6379, db=0): ...
3     def display_welcome(self): ...
4     def display_help(self): ...
5     def format_chirp(self, chirp): ...
6     def format_user(self, user): ...
7     def display_latest_chirps(self): ...
8     def display_top_followers(self): ...
9     def display_top_posters(self): ...
10    def post_new_chirp(self, username, text): ...
11    def like_chirp(self, chirp_id): ...
12    def rechirp(self, chirp_id): ...
13    def add_new_user(self, username, name): ...
14    def display_top_liked(self): ...
15    def display_top_rechirped(self): ...
16    def run(self): ...
```

Listing 7: ChirpApp class structure

## 5.2.3 Web Interface (Streamlit)

The Streamlit app provides a user-friendly web interface:

```
1 # Initialize the Redis model
2 @st.cache_resource
3 def get_model(): ...
4
5 # Main page components
6 st.title("Chirp")
7 st.subheader("Compact Hub for Instant Real-time Posting")
8
9 # Navigation
10 page = st.sidebar.radio("Go to", ["Home", "Post a Chirp", "Top Users", "About"])
11
12 # Page implementations (Home, Post a Chirp, Top Users, About)
13 if page == "Home":
```

```
14     # Display latest chirps, most liked, most rechirped
15     ...
16 elif page == "Post a Chirp":
17     # Form to post new chirps or add users
18     ...
19 elif page == "Top Users":
20     # Display top users by followers and chirps
21     ...
22 elif page == "About":
23     # About page content
24     ...
```

Listing 8: Streamlit app structure

## 5.3 Data Flow

### 5.3.1 Posting a New Chirp

The process of posting a new chirp involves:

1. The user submits text content via CLI or web interface
2. The application layer validates the input and calls the data model
3. The data model:
  - Generates a unique chirp ID based on timestamp
  - Creates a chirp hash with the text, user information, and metadata
  - Adds the chirp to the timeline sorted set with the timestamp as score
  - Increments the user's chirp count
  - Updates the top posters ranking
4. The application confirms the operation with feedback to the user

### 5.3.2 Retrieving Latest Chirps

When fetching the latest chirps:

1. The application requests latest chirps from the data model
2. The data model:
  - Queries the timeline sorted set for the most recent chirp IDs
  - Retrieves the full chirp data for each ID
  - Formats and returns the complete chirp objects
3. The application layer formats the chirps for display
4. The interface presents the formatted chirps to the user

## 5.4 Data Import Pipeline

A data import pipeline was developed to process Twitter data:

1. **processing.py** - Extracts English tweets from compressed JSON files
2. **import\_data.py** - Filters and imports tweets into Redis
3. **fix\_engagement.py** - Adds realistic engagement metrics

## 5.5 Implemented Functionalities

### 5.5.1 Core Features

- User profile management (creation, statistics)
- Posting new chirps (text-only messages)
- Viewing latest chirps timeline
- Viewing top users by followers
- Viewing top users by post count

### 5.5.2 Additional Features

- Engagement metrics (likes, rechirps)
- Top chirps by engagement (most liked, most rechirped)
- Web interface with Streamlit
- Data import capabilities
- Database reset functionality

## 6 Testing

---

### 6.1 Testing Strategy

A focused testing approach was implemented with:

- Unit tests for the Redis model core functionality
- Integration tests for the data import process
- Web interface tests using mocks for the model interactions

The testing framework uses:

- pytest as the test runner
- fakeredis for Redis mocking to avoid actual database operations
- unittest.mock for additional component mocking
- pytest-cov for coverage reporting and monitoring

### 6.2 Test Structure

The test suite is organized into three main modules:

```
1 tests/  
2 |-- test_import_data.py      # Tests for the data import process  
3 |-- test_redis_model.py      # Tests for the Redis data model  
4 '-- test_streamlit_app.py     # Tests for the web interface
```

Listing 9: Test suite organization

### 6.3 Test Coverage

The current test suite includes 18 tests that focus on key functionality:

- **Redis model (10 tests):** Core data model operations including user and chirp management, timeline generation, and engagement functionality
- **Import process (4 tests):** Data import validation, filtering, and error handling
- **Web interface (4 tests):** Key user interactions with the Streamlit application

### 6.4 Testing Results

The test suite covers the core functionality with a focus on the data layer. Results from the most recent test run:

```

```

Listing 10: Test execution results

The key coverage metrics show a strategic focus on the data model:

- Total tests: 18
- Total execution time: 0.62 seconds
- Core data model coverage: 75%
- Data import script coverage: 62%
- Overall project coverage: 23%

This coverage pattern reflects a deliberate prioritization of testing the data layer, which contains the most business-critical logic. Future test development would focus on increasing coverage of the UI components and utility scripts.

## 7 Conclusion and Future Work

---

### 7.1 Achievements

This project successfully implemented:

- A comprehensive key-value data model for a social media application
- Efficient data structures for timeline, user management, and rankings
- Both command-line and web interfaces
- Data import functionality
- Additional engagement features

The implementation demonstrates:

- Effective use of Redis data structures (hashes, sorted sets)
- Appropriate denormalization strategies
- Performance optimization through careful key design
- Clean separation of concerns in architecture

### 7.2 Challenges and Limitations

Several challenges were encountered:

- Modeling relationships in a key-value store requires denormalization
- Managing sorted sets for rankings requires careful transaction management
- Limited options for complex queries compared to relational databases
- Memory consumption of denormalized data

Current limitations of the implementation:

- No support for media content (images, videos)
- Limited user authentication and security
- No support for hashtags or mentions
- No support for chirp deletion or editing
- Limited search capabilities

### 7.3 Future Work

Potential improvements for future iterations include both feature expansions and technical improvements:

- **Feature enhancements:**
  - Implementing a follow/unfollow mechanism
  - Adding personalized user timelines
  - Supporting hashtags and topic trending
  - Implementing user mentions and notifications
  - Adding search functionality
  - Supporting chirp deletion and editing
  - Adding media content support
- **Technical improvements:**
  - Improving test coverage for UI components and utility scripts
  - Implementing continuous integration via GitHub Actions
  - Improving security with authentication
  - Implementing data sharding for scalability
  - Adding automated performance benchmarking
  - Implementing data backup and recovery mechanisms

### 7.4 Performance Considerations

A key aspect of future work would involve benchmarking and optimizing performance:

- Load testing with variable user counts and chirp volumes
- Memory usage optimization techniques
- Implementing caching strategies for frequently accessed data
- Exploring Redis Cluster for horizontal scaling

### 7.5 Lessons Learned

This project provided valuable insights into:

- Non-relational data modeling approaches
- Performance implications of different Redis data structures
- Trade-offs between normalization and query performance
- Importance of key design in key-value databases
- Benefits and limitations of key-value stores for social media applications

## 7.6 Conclusion

The Chirp project demonstrates that key-value databases like Redis can effectively support core social media functionalities with excellent performance characteristics. The implementation successfully met all the laboratory requirements while providing additional features to enhance the application's realism and usability.

The denormalized data model and careful selection of Redis data structures enabled efficient operations for timeline retrieval, user rankings, and chirp management. This approach highlights the strengths of key-value databases in handling high-throughput, real-time social media scenarios, while also illustrating the design considerations necessary when moving beyond traditional relational database models.

This project provides a solid foundation for further exploration of non-relational database technologies and their application in building scalable, real-time social platforms.
